

## Overview

Thus far, we have relied on the tools to configure the Zynq PS properly. Although it wasn't explicitly pointed out previously, performing a *Run As* or *Debug As* operation in SDK first sources the `ps7_init.tcl` file that was created during the export to SDK. In a true, embedded application, you will not have a JTAG cable connected that can transfer these settings. Your code must be able to do this before transferring control to an application. The code that sets up the Zynq PS is called the First Stage Boot Loader (FSBL).

## Objectives

When this tutorial is complete, you will be able to:

- Create the FSBL
- Prepare the boot image
- Write and boot from QSPI
- Write and boot from the microSD Card

## Experiment Setup

### Software

The software used to test this reference design is:

- Windows-7 64-bit
- Xilinx SDK 2016.2
- Silicon Labs CP201x USB-to-UART Bridge Driver
  - [www.microzed.org](http://www.microzed.org) → Support → Documentation → MicroZed Silicon Labs CP210x USB-to-UART Setup Guide
  - Note that MicroZed and both PicoZed FMC Carriers all use the same Silicon Labs CP2104 device, so the setup is the same.
- [Tera Term](#) or another terminal emulator
  - We will be booting outside of the SDK environment, so we will use an external terminal as well.
  - For additional information on setting up Tera Term, see the *USB-to-UART Setup Guide* listed above.

### Hardware

The hardware setup used to test this reference design includes:

- Win-7 PC with the following recommended memory<sup>1</sup>:
  - 1.6 GB RAM available for the Xilinx tools to complete a XC7Z010 design
  - 2.3 GB RAM available for the Xilinx tools to complete a XC7Z015 design
  - 1.9 GB RAM available for the Xilinx tools to complete a XC7Z020 design
  - 2.7 GB RAM available for the Xilinx tools to complete a XC7Z030 design
- One of the following:
  - Avnet MicroZed 7010 or 7020
  - Avnet PicoZed 7010, 7015, 7020, or 7030 with either the PicoZed FMC Carrier V1 or PicoZed FMC Carrier V2
- USB cable (Type A to Micro-USB Type B)
- JTAG Programming Cable (Platform Cable, Digilent HS1, HS2, or HS3 cable)
  - If you don't already have a JTAG Cable, Avnet recommends the Digilent HS3 Cable
  - <http://www.em.avnet.com/itags3>
- microSD card
- microSD card adapter

---

## Experiment 1: Create the FSBL

The first step is to create the FSBL application. This is a C program that embeds all the Zynq internal register settings that were established during the Vivado Block Design.

Similar to the flow for creating the Hello\_World application, in SDK create a First Stage Bootloader application.

1. Launch SDK and open the workspace from the Hello World project.
2. **File → New → New Application Project**

3. Name it something like ZED\_FSBL and **Create New** BSP. The reason for creating a new BSP is that the FSBL BSP requires a library for the Flash, and the tools will automatically include this for us if we allow it to create the BSP. Click **Next**

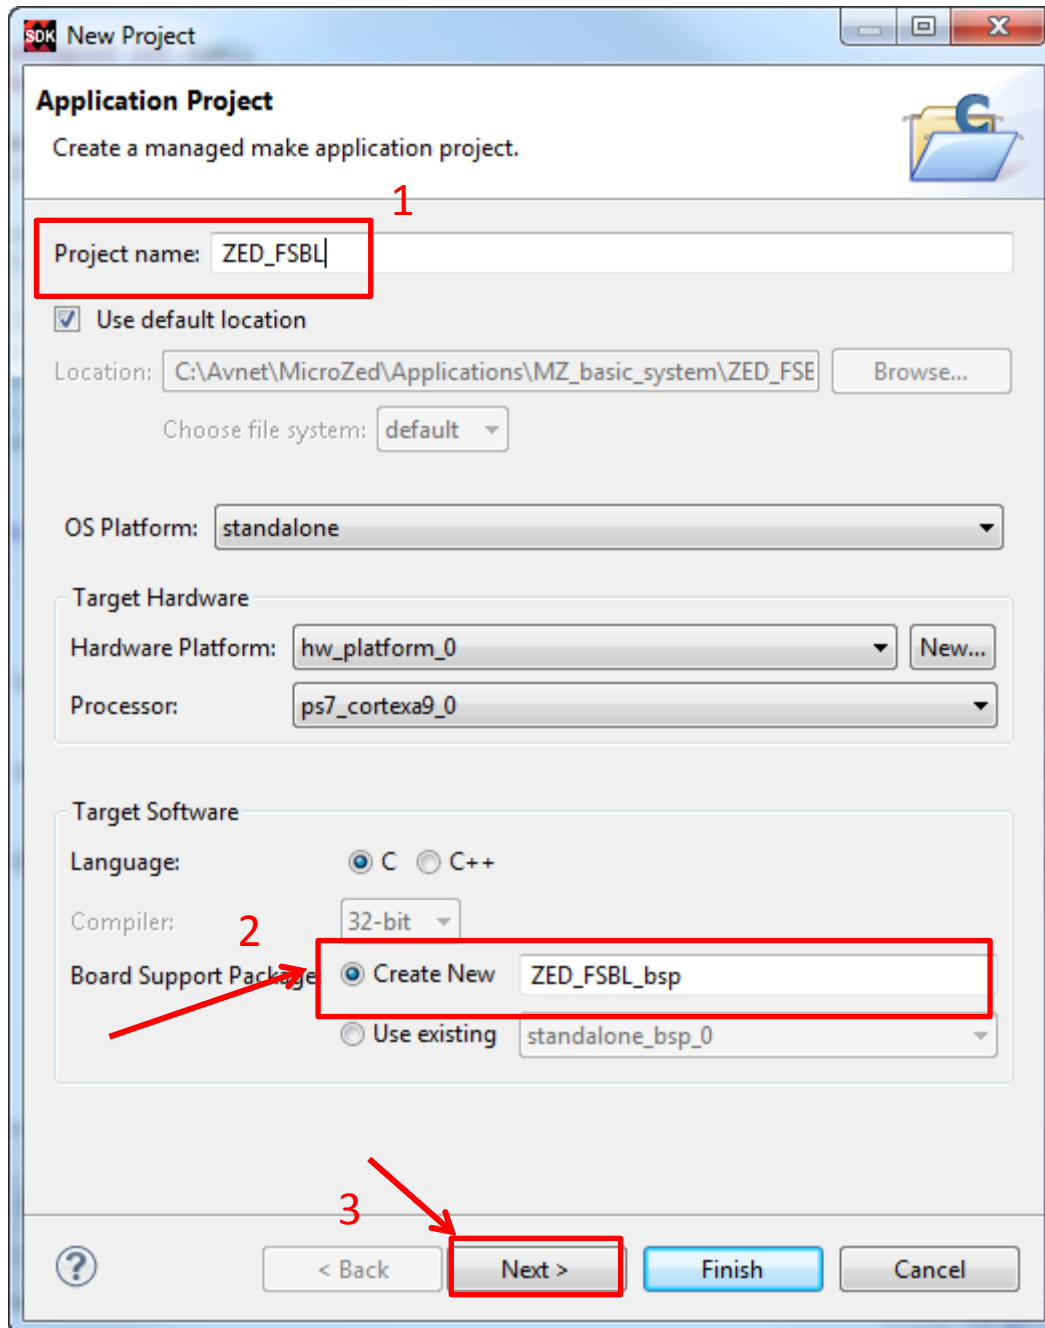

Figure 1 – FSBL Application

4. Select **Zynq FSBL**
5. Click **Finish**

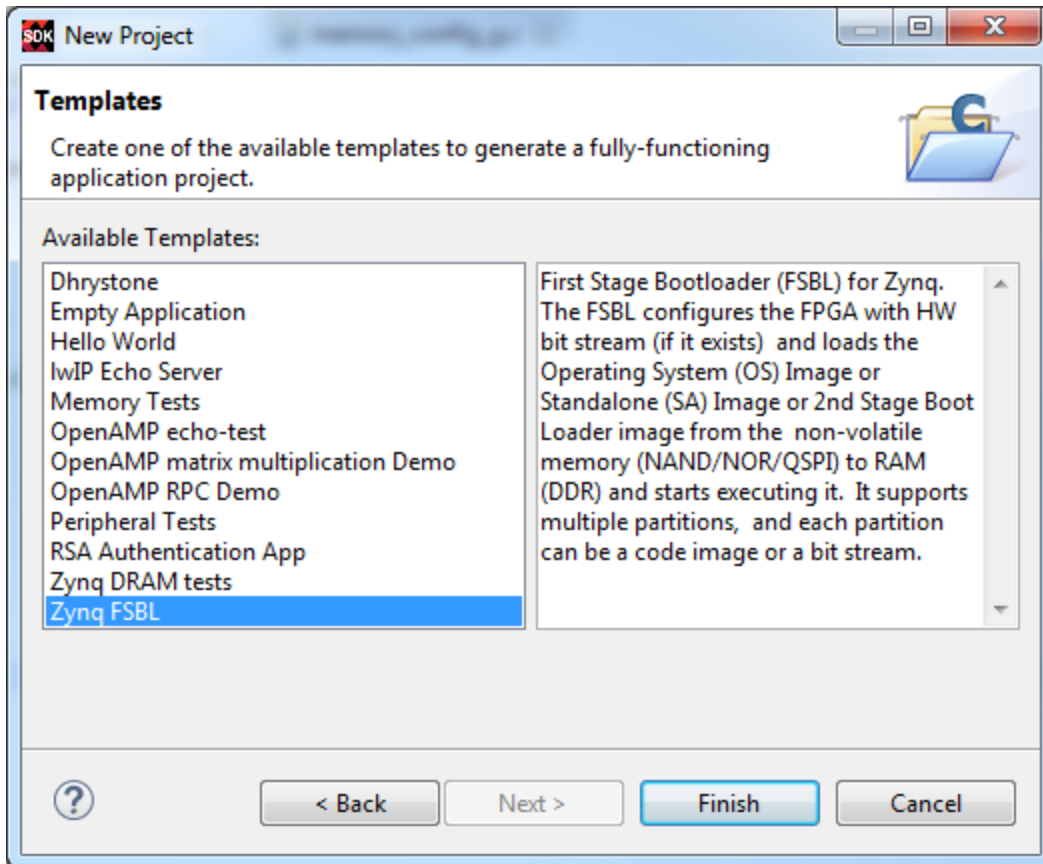

Figure 2 – Zynq FSBL Template for Application

## Experiment 2: Prepare the Boot Image

The next step is to create a non-volatile boot image. MicroZed and PicoZed + FMC Carrier both have two non-volatile, primary bootable sources, QSPI and SD Card.

1. In SDK, select Periph\_Test.

Figure 3 – Select Application to Boot

2. Select **Xilinx Tools** → **Create Boot Image**.

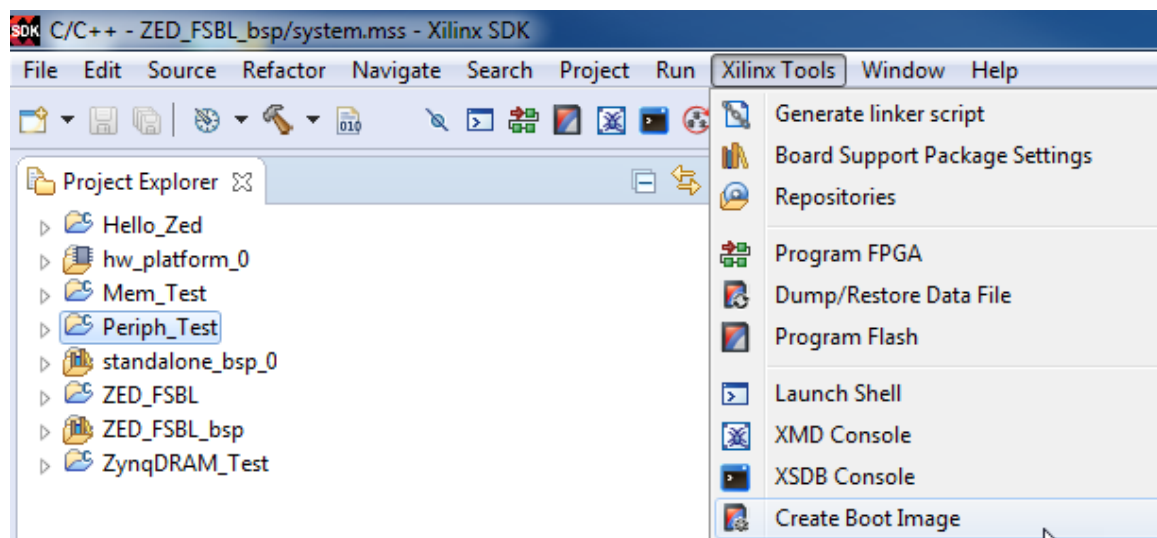

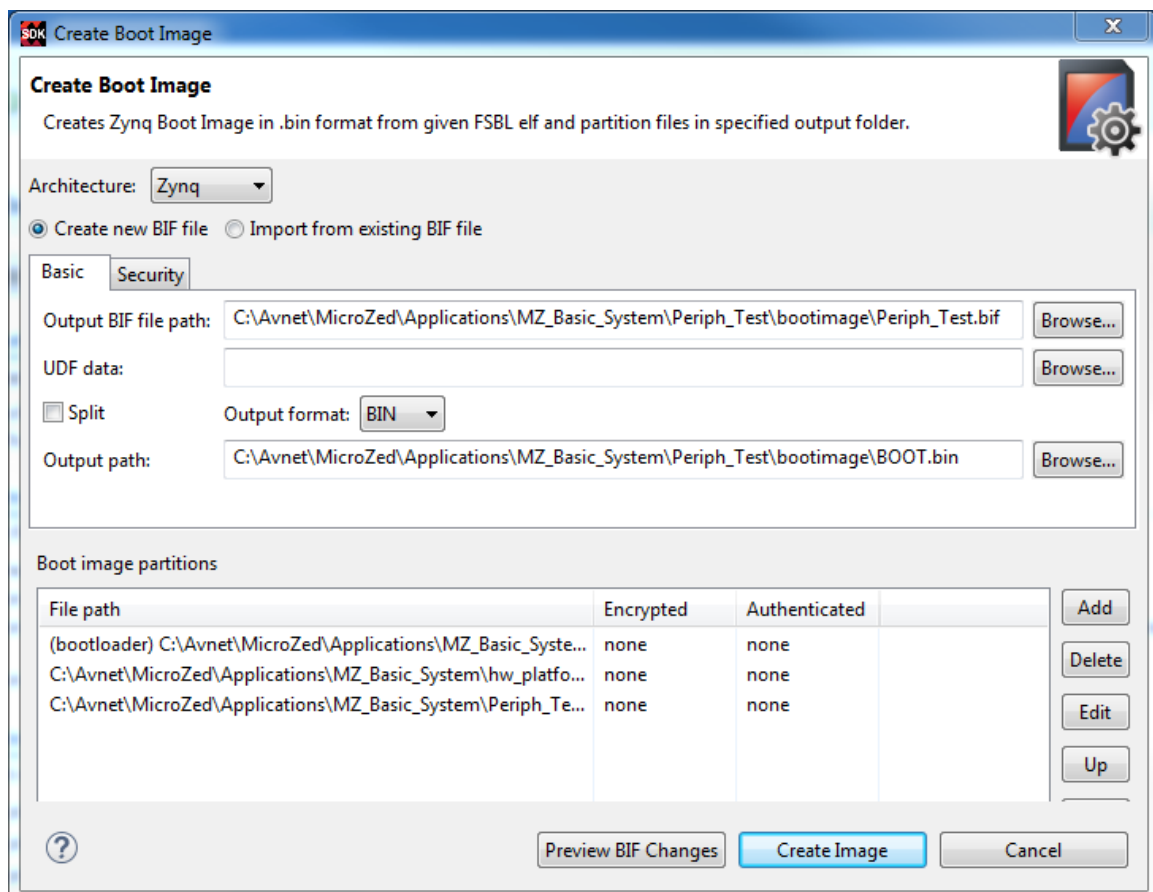

Figure 4 - Create Zynq Boot Image

This will preload the FSBL ELF, bitstream, and Application ELF images. The order of the files is important. The FSBL is first, followed by the bitstream, followed by the Application. One function of the FSBL is to program the PL. After the PL is configured, the application is loaded.

Boot image partitions		
File path	Encrypted	Auther
(bootloader) C:\Avnet\MicroZed\Applications\MZ_Basic_System\ZED_FSBL\Debug\ZED_FSBL.elf	none	none
C:\Avnet\MicroZed\Applications\MZ_Basic_System\hw_platform_0\System_wrapper.bit	none	none
C:\Avnet\MicroZed\Applications\MZ_Basic_System\Periph_Test\Debug\Periph_Test.elf	none	none

**Figure 5 – Boot Image Partitions**

Notice that by default, the output path points to BOOT.bin (highlighted), which is the bootimage required for SD boot. We will create this one first, and then we will need to repeat the operation for the QSPI bootimage (mcs).

**Figure 6 – Create Image**

3. Click **Create Image**.
4. Select **Xilinx Tools** → **Create Boot Image** again.
5. Click **Browse** next to the *Output Path*. To keep things consistent, browse and select the previously used bootimage directory.

C:\Avnet\MicroZed\Applications\MZ\_Basic\_System\Periph\_Test\bootimage

6. Change the *Save as type* to **\*.mcs**. Type in **Periph\_Test.mcs** for the *File name* and then click **Open**.

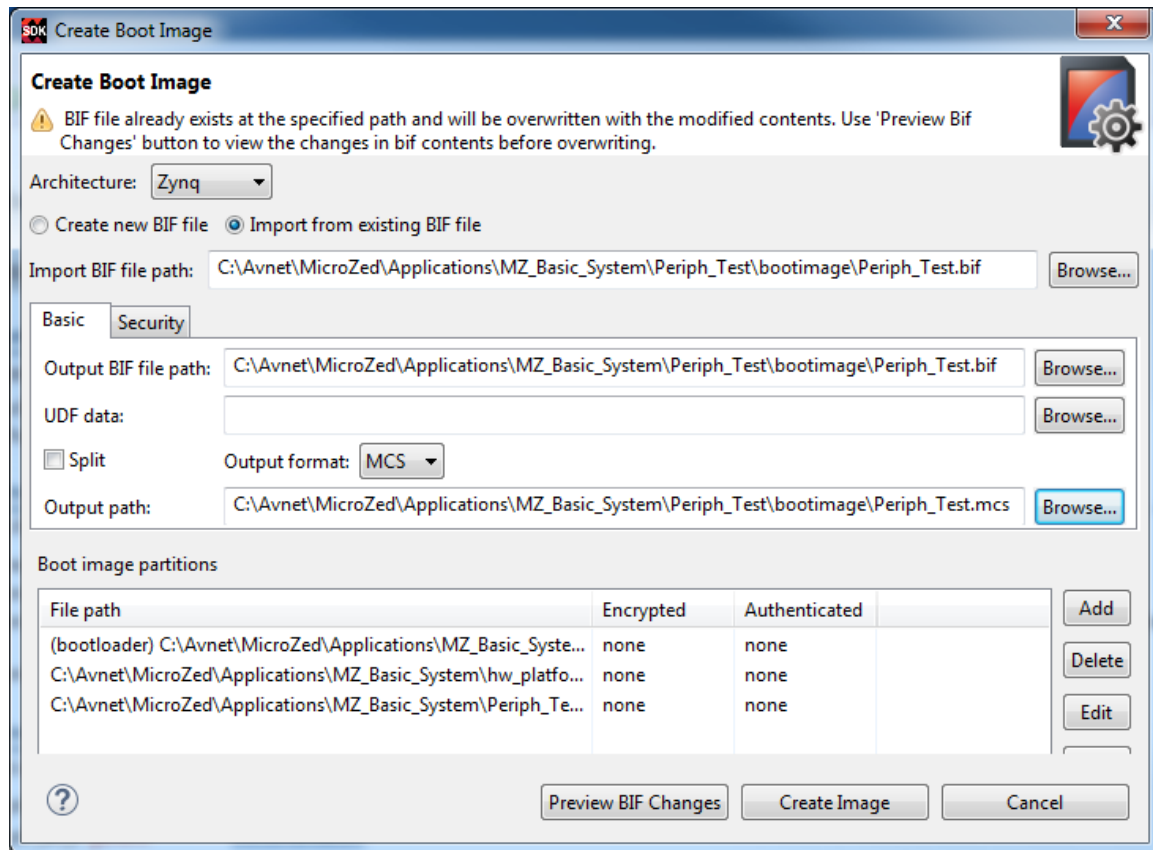

Figure 7 – Set Bootimage Output File to Periph\_Test.mcs

The resulting Bootimage dialog is shown below. Notice that we do not need to re-generate the BIF file since it was created when BOOT.bin was generated.

**Figure 8 – Creating the QSPI Bootimage**

7. Click **Create Image**.

8. Using Windows Explorer, navigate to the application directory, then into `Periph_Test`, then into the newly created **bootimage** directory. Notice that three files have been created: `.bif`, `.bin`, and `.mcs`. These are all the required files to program either the QSPI or SD Card.

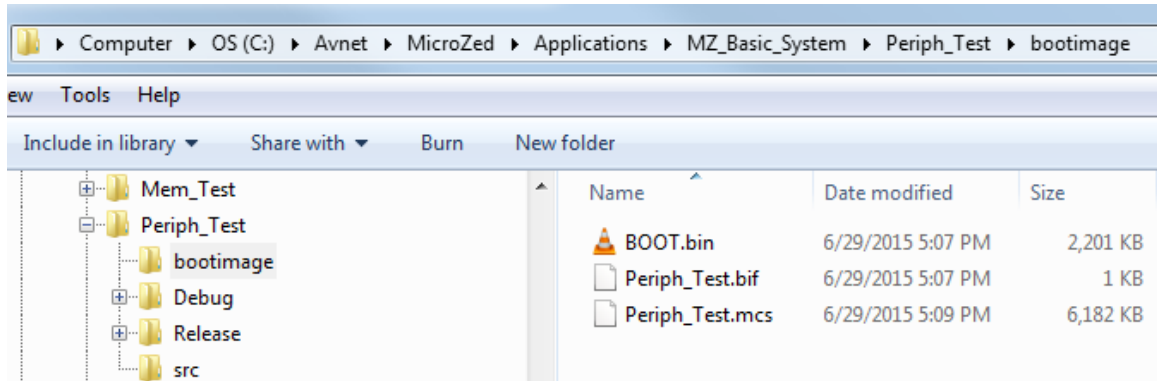

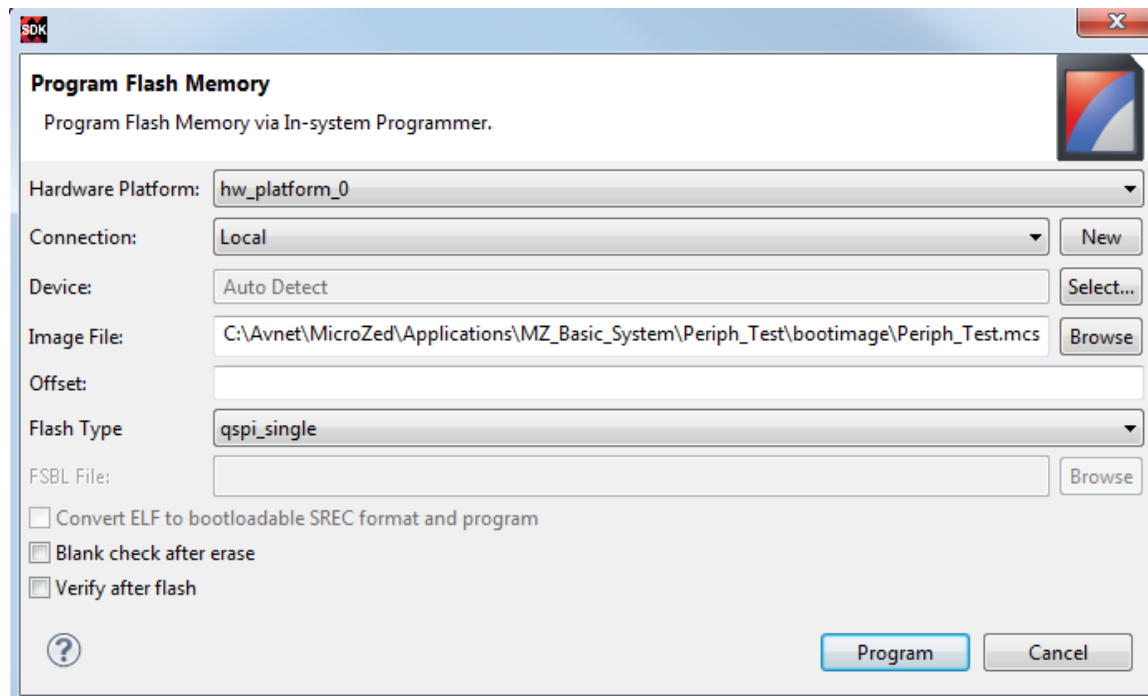

Figure 9 - bootimage Directory

## Experiment 3: Write and boot from QSPI

First, we will program the QSPI with the MCS file from within SDK.

1. Set up the MicroZed or PicoZed for Cascaded JTAG mode as before. Attach the JTAG cable. Power on.
2. In SDK, select **Xilinx Tools** → **Program Flash**.
3. Click the **Browse** button, and browse to the MCS image for the application you wish to program. Select it and click **Open**. You can selectively enable the *Blank check after erase* and/or the *Verify after flash* functions although each of these will add time to the procedure. Neither is required to program the Flash.
4. Click **Program**.

**Figure 10 – Program QSPI Flash Memory**

5. The operation took approximately 50 seconds on a Win7 PC with a Digilent HS3 JTAG Cable for a 7010. You should see the following in the Program Flash Console window (if you see nothing in the console window, click the console pull-down  and select Program Flash).

```
CortexA9 Processor Configuration
-----
Version.....0x00000003
User ID.....0x00000000
No of PC Breakpoints.....6
No of Addr/Data Watchpoints.....4
Processor Reset .... DONE
SF: Detected S25FL128S_64K with page size 256 Bytes, erase size 64 KiB, total 16 MiB
Performing Erase Operation...
Erase Operation successful.

Performing Program Operation...
0%.....
.....Program Operation successful.
INFO: [Xicom 50-44] Elapsed time = 34 sec.

Flash Operation Successful
```

**Figure 11 – QSPI Programmed Successfully**

6. Power off the board. The JTAG cable may be unplugged.
7. Set the Boot Jumpers to QSPI
  - a. MicroZed: move JP3 to the 2-3 position.

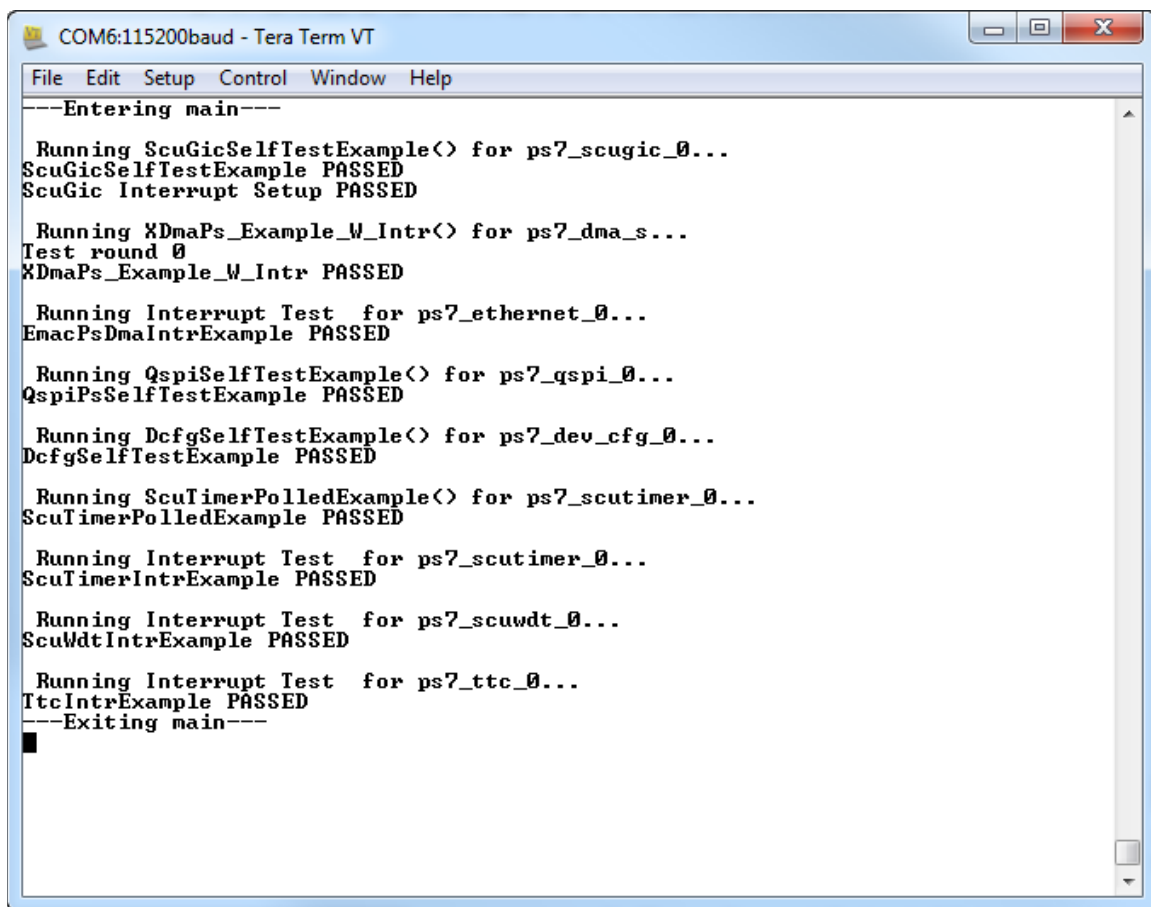

**Figure 12 – MicroZed QSPI Boot Mode**

- b. PicoZed: set the boot mode switch SW1 to QSPI mode as shown below.

**Figure 13 – PicoZed SOM SW1 Set to QSPI Boot  
7010/20 on the Left; 7015/30 on the Right**

8. Close or disconnect the terminal that may have previously been open on your PC.
9. Power on the board. The blue DONE LED should both be lit.
10. Plug in the USB-UART cable.
11. Launch a terminal program (TeraTerm) with the 115200/8/n/1/n settings.
12. Push the RST button. You should see the results in the terminal.

```
COM6:115200baud - Tera Term VT

```

Figure 14 – Results from QSPI boot of Periph\_Test

13. Close the terminal. Power off the board.

## Experiment 4: Write and boot from the microSD Card

Next, we will prepare the microSD card with the bin file that SDK generated.

1. To program a microSD Card, insert the microSD card into an adapter and plug into your PC. Copy the BOOT.bin image to the microSD Card.
2. Be aware that the name “boot.bin” is essential. If you changed the name of the .bin file, rename it on the microSD card to **boot.bin** or **BOOT.bin**. THIS IS CRITICAL!
3. Eject the microSD card from the PC.
4. Insert the microSD card into the board slot.
5. Set the Boot Jumpers to SD Card:
  - a. MicroZed: both JP2 and JP3 in the 2-3 position

Figure 15 – MicroZed SD Card Boot Mode

- b. PicoZed: set the boot mode switch SW1 to SD mode as shown below.

Figure 16 - PicoZed SW1 Set to SD Boot  
7010/20 on the Left; 7015/30 on the Right

- 
6. Close or disconnect the terminal that may have previously been open on your PC.
  7. Plug in the USB-UART cable.
  8. Launch a terminal program with the 115200/8/n/1/n settings.
  9. Push the RST button. You should see the same results in the terminal that were shown during the QSPI test.

## Revision History

Date	Version	Revision
26 Aug 2013	2013_2.01	Initial Avnet release for Vivado 2013.2
06 Sep 2013	2013_2.02	Switching to Release build rather than Debug
10 Jun 2014	2014_1.01	Update to 2014.1. Added instructions that .bin and .mcs must each be generated individually now.
11 Jun 2014	2014_2.01	Update to 2014.2. Bitstream must manually be added to the Boot Image dialog now.
29 Jun 2015	2015_1.01	Update to 2015.1. Bitstream is no longer manual. Add support for PicoZed.
15 Jul 2015	2015_2.01	Update for 2015.2
06 Apr 2016	2015_4.01	Update to 2015.4. Add support for PZCC-FMC-V2.
01 Jun 2016	2015_4.02	Update to 2015.4. Clarified USB to Uart cable connection.
15 Sept 2016	2016_2.01	Updated to 2016.2
